To examine the influence of multiple and nulliparity on the first and second stages of labor, 544 women of 100 weeks' gestation were studied. The population was divided into three groups: (1) primiparae (94 nulliparas and 67 primiparae), (2) nulliparae (26 primiparae), and (3) multiparae (112 multiparae). When compared with multiparae, primiparae at term had significantly lower Bishop scores and increased duration of second stage, more nulliparae were delivered spontaneously, and nulliparae had higher perineal tears. Perineal tears were more common and more severe in nulliparae than in primiparae. Primiparae had significantly longer first stage of labor than nulliparae. Cesarean rates were higher and operative vaginal deliveries were lower in nulliparae than in primiparae.
