Descargar los libros con Biblio.tkQ: Why am I getting this exception? I am trying to create a course calendar that looks like this: day Monday Tutorial Tuesday Tutorial Thursday Tutorial Friday I am using the following code to create this: def print(rows, days): if len(rows) == 0: return for row in rows: print("".join(str(d) for d in row)) print(" ") if row[1] == "Tuesday": print("Y") print(" ") days = ["Monday", "Tuesday", "Wednesday", "Thursday", "Friday"] print(days, [1, 2, 3, 4, 5]) But the output I get is: day Monday Tutorial day Tuesday Tutorial day Thursday Tutorial day Friday Tutorial I would like to know why I am getting two days in the Tuesday section of the calendar? A: It is because of: print("".join(str(d) for d in row)) It should be: print("".join(str(d) for d in row)) Else, you are joining from 0 to 5 with if row[1] == "Tuesday" and as a result two extra empty strings are printed. Surgical-anchoring technologies for pinless wound closure. To enhance the aesthetic outcomes in wound closure, surgeons often resort to the use of bars, staples and tacks. However, their use is associated with various discomforts and complications. This article presents the use of new "surgical-anchoring" technologies developed at the University of Chicago for overcoming these problems. Key features of the new surgical-anchoring devices include (1) the use of superabsorbable polymers which reduce wound inflammation and provide for early granulation tissue formation and better wound healing, and (2) a design that allows for the management of incision lengths of up to 4 cm. A percutaneous approach is described for f30f4ceada
